# Инфраструктурные платформы

# Определение

**Инфраструктурная платформа** – совокупность систем, сервисов, людей, практик и соглашений, направленная на обеспечение этапов разработки и эксплуатации цифровых продуктов.

# Традиционный подход

Пример: продуктовой команде понадобилось новое окружение  
Каждый этап выполняется разными сотрудниками/командами

# Традиционный подход – орг. структура

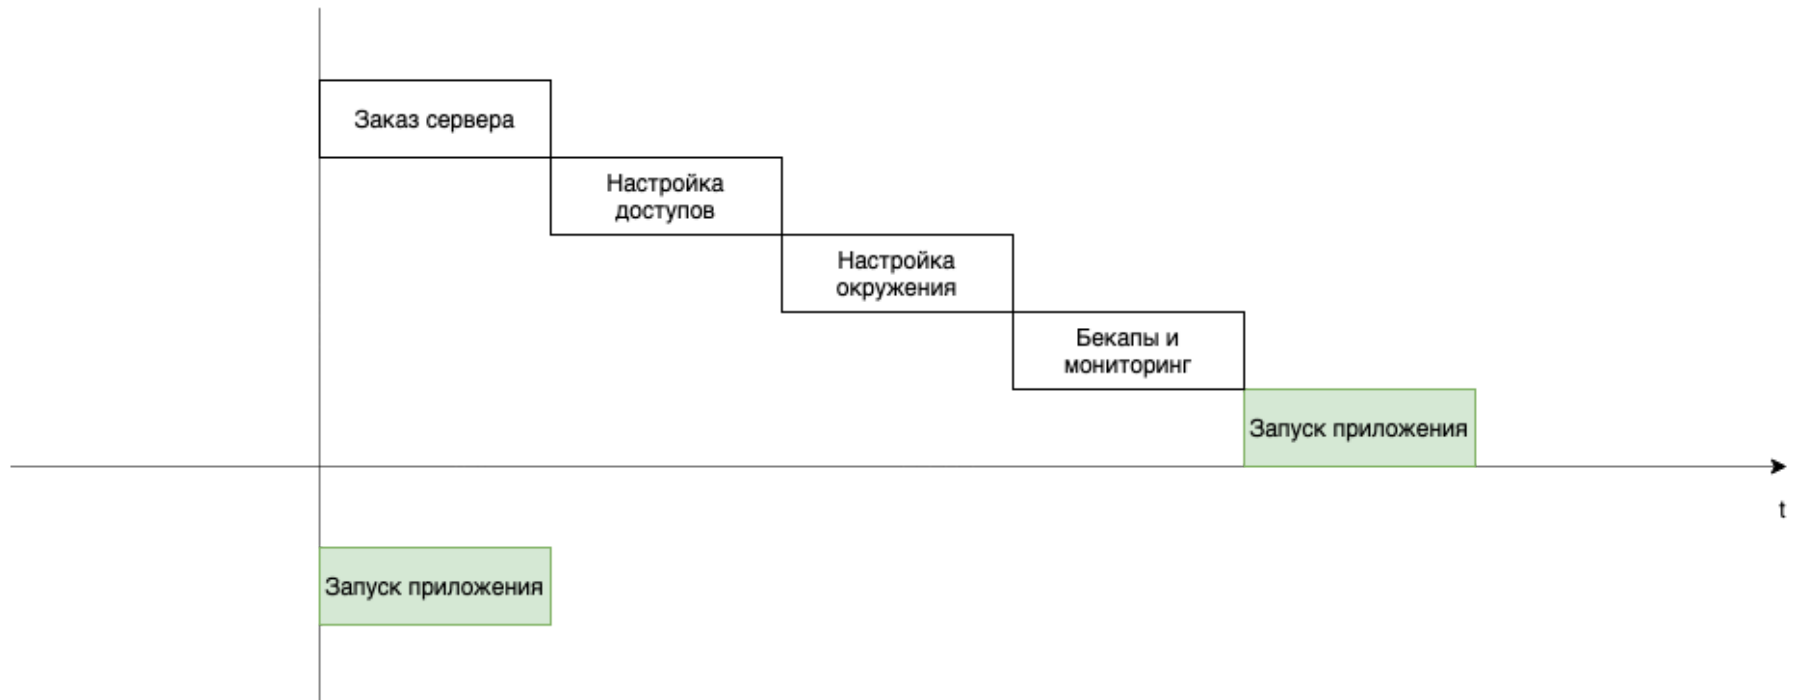

Эти сотрудники не заинтересованы в благополучии продукта

У них своя очередь задач и пожаров и свои KPI

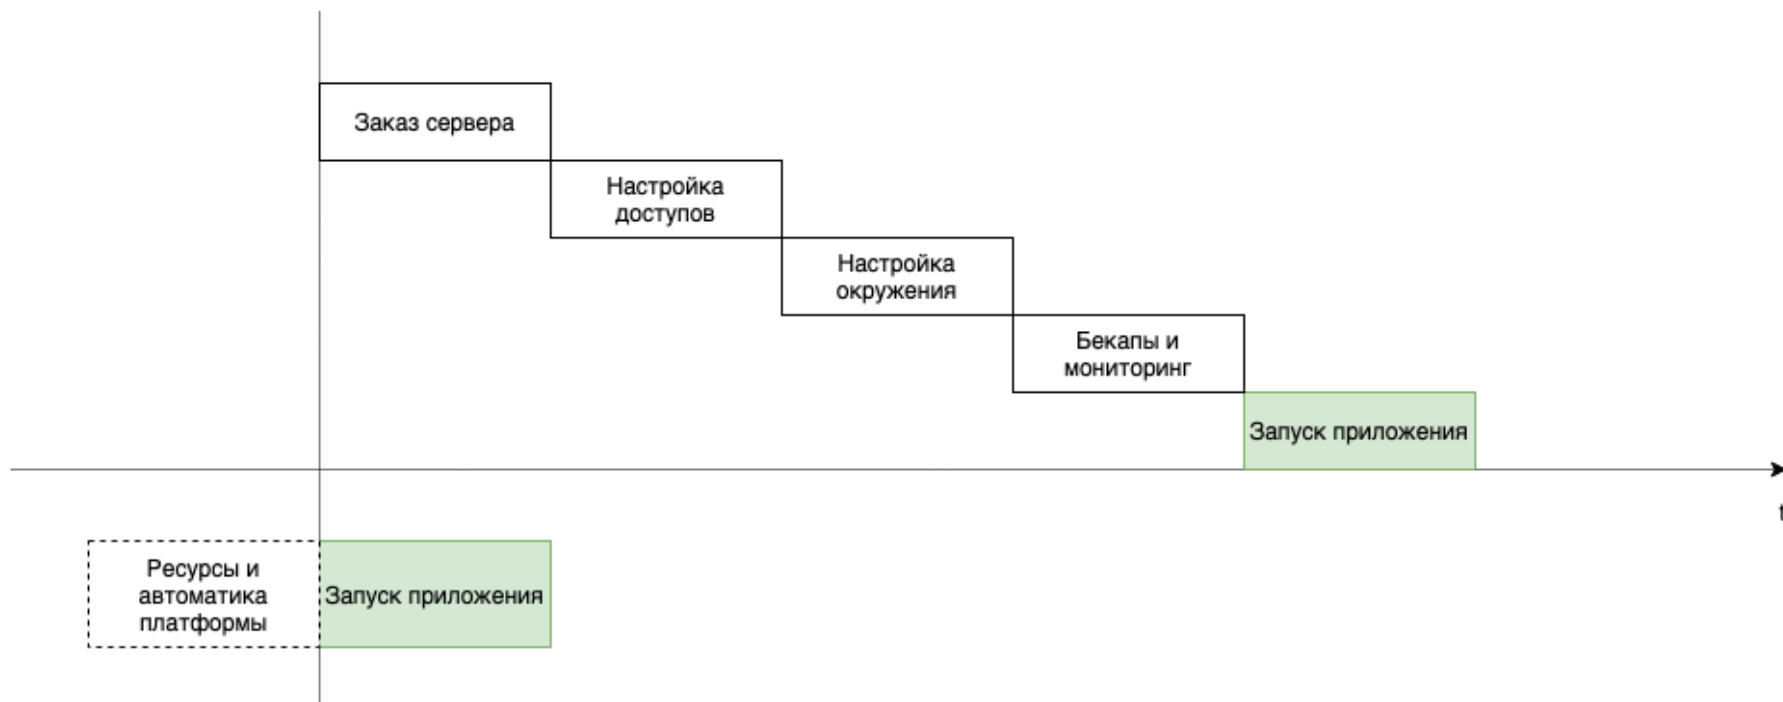

# Традиционный подход – скорость

# Традиционный vs Платформенный

Процедуры разработаны и автоматизированы заранее

- Требуются дополнительные компетенции
- Дополнительная когнитивная нагрузка
- Пересечения зон ответственности
- Сложнее быстро принимать решения
- Большое количество необходимых коммуникаций

## Platform as a Service

Another way to provide a better service to application developers is through implementing a platform as a service (PaaS) in which “the consumer does not manage or control the underlying cloud infrastructure including network, servers, operating systems, or storage, but has control over the deployed applications and possibly configuration settings for the application-hosting environment.”<sup>16</sup> Examples of a PaaS include Heroku, RedHat OpenShift, Azure App Service, Google App Engine, AWS Elastic Beanstalk and Cloud Foundry.

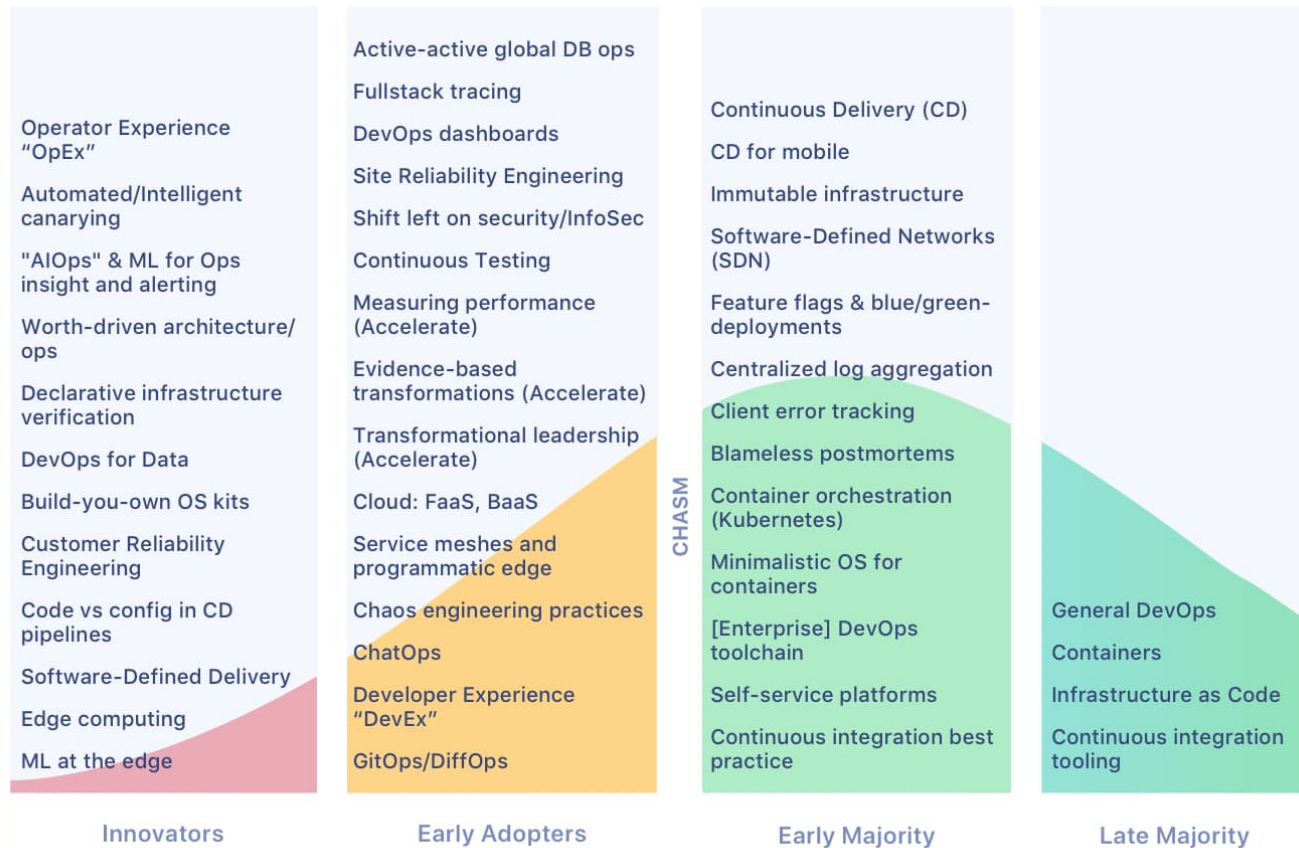

Only 24 percent of respondents report using a PaaS. However, respondents that do most of their work on a PaaS are 1.5 times more likely to be in the elite performance group. These respondents agreed or strongly agreed that their team uses libraries and infrastructure defined by the PaaS as the basis for their applications, can deploy their application into the cloud on demand using a single step, and can perform self-service changes on-demand for databases and other services required by their application.

Enterprises that achieve initial success with DevOps initiatives often struggle to scale their efforts. I&O leaders should dedicate teams to operating shared self-service platforms that enable agile product teams to accelerate delivery while ensuring quality and standardization.

By 2023, 90% of enterprises will fail to scale DevOps initiatives if shared self-service platform approaches are not adopted.

## Large-scale cluster management at Google with Borg

Google Inc.

### Abstract

Google's Borg system is a cluster manager that runs hundreds of thousands of jobs, from many thousands of different applications, across a number of clusters each with up to tens of thousands of machines.

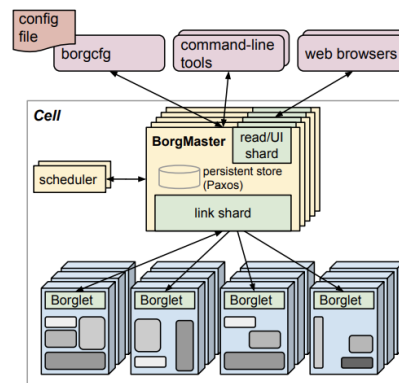

It achieves high utilization by combining admission control, efficient task-packing, over-commitment, and machine sharing with process-level performance isolation. It supports high-availability applications with runtime features that minimize fault-recovery time, and scheduling policies that reduce the probability of correlated failures. Borg simplifies life for its users by offering a declarative job specification language, name service integration, real-time job monitoring, and tools to analyze and simulate system behavior.

We present a summary of the Borg system architecture and features, important design decisions, a quantitative analysis of some of its policy decisions, and a qualitative examination of lessons learned from a decade of operational experience with it.

### 1. Introduction

The cluster management system we internally call Borg admits, schedules, starts, restarts, and monitors the full range of applications that Google runs. This paper explains how.

Borg provides three main benefits: it (1) hides the details of resource management and failure handling so its users can focus on application development instead; (2) operates with very high reliability and availability, and supports applications that do the same; and (3) lets us run workloads across tens of thousands of machines effectively. Borg is not the first system to address these issues, but it's one of the few operating at this scale, with this degree of resiliency and com-

cluding with a set of qualitative observations we have made from operating Borg in production for more than a decade.

### 2. The user perspective

Borg's users are Google developers and system administrators (site reliability engineers or SREs) that run Google's applications and services. Users submit their work to Borg in the form of *jobs*, each of which consists of one or more *tasks* that all run the same program (binary). Each job runs in one Borg *cell*, a set of machines that are managed as a unit. The remainder of this section describes the main features exposed in the user view of Borg.
